HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

PIECEWISE CERTIFICATES OF POSITIVITY FOR MATRIX POLYNOMIALS

RONAN QUAREZ

ABSTRACT. We show that any symmetric positive definite homogeneous matrix polynomial $M \in \mathbb{R}[x_1, \dots, x_n]^{m \times m}$ admits a piecewise semi-certificate, i.e. a collection of identities $M(x) = \sum_j f_{i,j}(x) U_{i,j}(x)^T U_{i,j}(x)$ where $U_{i,j}(x)$ is a matrix polynomial and $f_{i,j}(x)$ is a non negative polynomial on a semi-algebraic subset S_i , where $\mathbb{R}^n = \cup_{i=1}^r S_i$. This result generalizes to the setting of biforms.

Some examples of certificates are given and among others, we study a variation around the Choi counterexample of a positive semi-definite biquadratic form which is not a sum of squares. As a byproduct we give a representation of the famous non negative sum of squares polynomial $x^4 z^2 + z^4 y^2 + y^4 x^2 - 3x^2 y^2 z^2$ as the determinant of a positive semi-definite quadratic matrix polynomial.

1. INTRODUCTION

The Hilbert 17-th problem asks if a non negative polynomial $f(x) \in \mathbb{R}[x_1, \dots, x_n]$ is a sum of squares. The answer given by Artin provides an identity with denominators (or rational functions), namely there are two sums of squares of polynomials $q(x)$ and $p(x)$ such that $q(x)f(x) = p(x)$.

Such an identity is called Positivstellensatz and can be seen as a *certificate* which algebraically proves the positivity of the polynomial $f(x)$. For a general polynomial, the denominator $q(x)$ is necessary.

One may also consider a "relative" version, namely when $f(x)$ is non negative on a basic semi-algebraic subset $S = \{x \in \mathbb{R}^n \mid f_1(x) \geq 0, \dots, f_r(x) \geq 0\}$. This search of certificates received a lot of contributions especially for those semi-algebraic subsets S where the Positivstellensatz is denominator free. Essentially it happens to be possible when $f(x)$ is positive and when the description of S satisfies some archimedean property (which can be seen as a "strong" compactness assumption). Among all the available references, we mention the seminal works of Schmüdgen [10] and Putinar [8].

Another natural and often difficult question is, when it is possible to obtain a certificate of positivity, to study its complexity, i.e. the number of squares that are needed.

In this paper, we are mainly interested in matrix polynomials, namely polynomials whose coefficients are matrices. Let $x = (x_1, \dots, x_n)$ and $\mathbb{R}[x]^{m \times m}$ be the set

Key words and phrases. Biforms ; Matrix polynomials ; Positive semi-definite ; Positivity certificate ; Sum of Squares.

of all square matrix polynomials of size m with entries in $\mathbb{R}[x]$. In that context, by a square we mean an expression of the form $U(x)^T U(x)$ where $U(x) \in \mathbb{R}[x]^{m \times m}$, sometimes we will also use the terminology of *hermitian* square.

Given a symmetric matrix polynomial $M(x)$, the natural question is the following :

Assume that $M(x)$ is positive semi-definite (*psd* in short) for all $x \in \mathbb{R}^n$. Is $M(x)$ a sum of hermitian squares ? Or in other words, do we have a positivity certificate for $M(x)$?

It is well known that, when $n = 1$, then $M(x)$ is a sum of two squares (see for instance [4] for a proof), i.e. $M(x) = U(x)^T U(x) + V(x)^T V(x)$ where $U(x), V(x) \in \mathbb{R}[x]^{m \times m}$.

There is also another case where we have a positive answer : the case of bi-quadratic forms in dimension 2. Namely, if $m = 2$ and if the entries are homogeneous polynomials of degree 2, then $M(x)$ is also a sum of squares.

In fact this last case can be seen as a particular case of the homogenized version of the previous one (see [2] for this fact and a proof).

Unfortunately these are essentially the only cases where such a certificate exists for a matrix polynomial. For instance, it becomes false even for bi-quadratic forms in 3 variables and dimension 3 (confer the Choi counterexample in [1]).

We may also look at the relative situation : if $M(x)$ is positive definite for all x in a semi-algebraic subset $S \subset \mathbb{R}^n$ whose description satisfies an archimedean property, then we get a similar certificate as in the polynomial case. This has been proved by Hol and Scherer in [6] ; see also [7] for a different and more algebraic proof.

In this paper, we are searching for certificates of positivity *without denominators* for matrix polynomials. We first study certificates which are sums of squares of matrix polynomial weighted by a psd (scalar) polynomial. More precisely, given a psd matrix polynomial $M(x)$, we wonder if $M(x)$ can be written as a finite sum

$$(1) \quad M(x) = \sum_i f_i(x) U_i(x)^T U_i(x)$$

where $U_i(x) \in \mathbb{R}[x]^{m \times m}$ and $f_i(x)$ is non negative polynomial on \mathbb{R}^n .

We call it a *semi-certificate* since, roughly speaking, we have a certificate which is a hermitian sum of squares weighted by some coefficients which are non negative polynomials.

Of course such a certificate may give some others which will be totally algebraic by using usual certificates for the psd polynomials $f_i(x)$. Beware that using denominators at this point could break any interest since we may readily get one such certificate with denominators simply by using the Gauss algorithm (indeed, it suffices to invert the $m - 1$ first principal minors of the given matrix polynomial). Although, when the matrix polynomial is positive definite, a relative version of semi-certificate with respect to a semi-algebraic subset S whose description is archimedean would produce a usual denominator free algebraic certificate for the matrix polynomial on S , using for instance Schmüdgen or Putinar certificates for all the $f_{i,j}$'s.

Unfortunately such a semi-certificate as in (1) does not exist in general, even for a positive definite matrix polynomial, as it is illustrated in section 3.

Nevertheless, noticing that one may obtain such certificate locally, we introduce the notion of *piecewise* semi-certificate, i.e. a collection of semi-certificates as in (1) with respect to a semi-algebraic covering of \mathbb{R}^n .

We show in section 4, that such a certificate exists for any *positive definite* homogeneous matrix polynomial. We show also that we may translate the notion of semi-certificate and our related results to the case of biforms.

Some examples and counterexamples are given and for instance, in section 5, we study some variations around the Choi counterexample given in [1].

As a byproduct we give a representation of the famous psd non sum of squares polynomial $x^4z^2 + z^4y^2 + y^4x^2 - 3x^2y^2z^2$ as the determinant of a psd quadratic matrix polynomial.

Of course, a lot a work have to be done to better understand the framework of semi-certificate for psd non definite matrix polynomials. Moreover, concerning complexity, one may be interested in estimating the lenght of the hermitian sum of squares representation, and also in the number of pieces of the semi-certificate. Since we use a compactedness argument, no bound on the number of pieces of the semi-algebraic covering can be derived by our method.

2. NOTATIONS

2.1. Matrix polynomials and biforms. In all the paper, we consider a set of variables $x = (x_1, \dots, x_n)$ and the polynomial ring $\mathbb{R}[x]$ whose associated field of rational functions is $\mathbb{R}(x)$.

A matrix polynomial $A(x)$ is just a matrix whose entries are polynomials. For instance, for a square matrix polynomial of size m in the variables x , we write $A(x) \in \mathbb{R}[x]^{m \times m}$.

A *form* of type (n, d) will denote an homogeneous polynomial of degree d in n variables. A *biform* of type $(n_1, d_1; n_2, d_2)$ will denote a homogeneous polynomial in $n_1 + n_2$ variables which is of degree d_1 with respect to a set of n_1 variables and of degree d_2 with respect to the other set of d_2 variables.

To a matrix polynomial $A(x) = (a_{i,j}(x)) \in \mathbb{R}[x]^{m \times m}$ whose entries are all forms of type (n, d) , we may canonically associate a biform of type $(n_1, d_1; m, 2)$:

$$f_A(x, y) = \sum_{1 \leq i, j \leq m} a_{i,j}(x) y_i y_j.$$

We say that a biform of type $(n_1, d_1; n_2, d_2)$ is *positive definite* if $f(x, y) > 0$ for all $(x, y) \in S^{n_1-1} \times S^{n_2-1}$, where S^{k-1} denotes the k_1 dimensional unit sphere in \mathbb{R}^k . Equivalently, we may alternatively consider the product of projective spaces instead of unit spheres.

If $A(x)$ is a symmetric matrix polynomial in $\mathbb{R}[x]^{m \times m}$ whose entries are all forms of type (n, d) , we say that $A(x)$ is positive definite if the associated biform $f_A(x, y)$ is positive definite. We may also note that $A(x)$ is psd if and only if $f_A(x, y)$ is psd on the product of unit spheres.

2.2. Sum of squares and Hilbert 17th problem. Note that sums of hermitian squares when dealing with matrix polynomials corresponds to usual sum of squares in the terminology of biforms.

Let $A(x)$ be a symmetric matrix polynomial in $\mathbb{R}[x]^{m \times m}$ which is positive semi-definite for all substitution of $x \in \mathbb{R}^n$. Then, the Gauss reduction algorithm gives a solution with denominators to the Hilbert 17-th Problem for a generic matrix polynomial : there exist $r \in \mathbb{N}$, $U_1(x), \dots, U_r(x) \in \mathbb{R}[x]^{m \times m}$ and $f_1(x), \dots, f_r(x), f(x) \in \mathbb{R}[x]$ psd polynomials such that

$$(2) \quad f(x)A(x) = \sum_{i=1}^r f_i(x)U_i(x)^T U_i(x)$$

where $f(x)$ can be chosen as the product of the $m - 1$ first minors of $A(x)$ when they do not identically vanish. Moreover, by multiplying the identity (2) by the denominators appearing in a positivity certificate for the f_i 's, we may assume that the polynomials f_i and f are sum of squares.

In our paper, we are mainly interested in positivity certificates without denominators, namely when we may choose $f \equiv 1$. Hence, we first look for matrix polynomials which can be written as in (1) :

$$A(x) = \sum_{i=1}^r f_i(x)U_i(x)^T U_i(x)$$

where the f_i 's are non-negative polynomials (we cannot ask for them to be sum of squares since denominators are already needed for polynomials).

One may want to measure the complexity of the certificate given in (1), simply by counting the number of squares : r . But, one may also prefer another way of counting.

Noticing that $U^T U = U^T (E_1 + \dots + E_m) U = (E_1 U)^T (E_1 U) + \dots + (E_m U)^T (E_m U)$ where E_i is the diagonal matrix whose only non null entry is 1 at the i -th position onto the diagonal, we may prefer to count "rank-one" sums of squares, i.e. when $U(x)$ has rank one in $\mathbb{R}(x)^{m \times m}$. The advantage of that count is that it coincides with the number of needed squares when we view our matrix polynomial as a biform.

3. SEMI-CERTIFICATES

The following examples shows that it is not possible in general to hope for (1).

3.1. Some examples.

Example 3.1. Let :

$$M = \begin{pmatrix} 1 + x^2 & xy \\ xy & x^2 + y^4 \end{pmatrix}$$

Of course M is psd for all $(x, y) \in \mathbb{R}^2$.

To show that M cannot be written as in (1), we may proceed by applying to the biform f_M which is canonically associated to M the technology of cages and Gram matrices developped in [3]. But we prefer to produce here an elementary and self-contained argument.

Assume that $M = \sum_{i=1}^r f_i U_i^T U_i$, where $U_i \in (\mathbb{R}[x, y])^{2 \times 2}$ and $f_i \geq 0$ on all \mathbb{R}^2 .

By decomposing into rank one sum of squares, we may assume that

$$U_i^T U_i = \begin{pmatrix} a_i^2 & a_i b_i \\ a_i b_i & b_i^2 \end{pmatrix}, \quad \text{where } a_i, b_i \in \mathbb{R}[x, y].$$

Identifying the $(1, 1)$ -entry, we get $\sum_{i=1}^r f_i a_i^2 = 1 + x^2$. Thus, f_i does not depend on y : $f_i \in \mathbb{R}[x]$. Since $f_i \geq 0$ for all $x \in \mathbb{R}$, we deduce that f_i is a sum of two squares in $\mathbb{R}[x]$. Thus, if we increase the integer r and if we change the U_i 's, we may assume that $f_i = 1$. Identifying the entries, we get

$$\begin{cases} \sum_{i=1}^r a_i^2 &= 1 + x^2 \\ \sum_{i=1}^r b_i^2 &= x^2 + y^4 \\ \sum_{i=1}^r a_i b_i &= xy \end{cases}$$

By a simple degree consideration, the polynomial b_i has necessarily the form

$$b_i = \alpha_i x + \beta_i y^2, \quad \text{with } \alpha_i, \beta_i \in \mathbb{R}.$$

Likewise, the polynomial a_i has necessarily the form

$$a_i = \gamma_i + \delta_i x \quad \text{with } \gamma_i, \delta_i \in \mathbb{R}.$$

It follows a contradiction with the identity $\sum_{i=1}^r a_i b_i = xy$.

The previous pathology is not due to the fact that the matrix M is only psd, as shown by considering the following variation :

Example 3.2. Let

$$N = \begin{pmatrix} 1 + x^2 + \epsilon(x^4 + y^4) & xy \\ xy & \epsilon(1 + x^4) + x^2 + y^4 \end{pmatrix}$$

where $\epsilon > 0$. This is a positive definite matrix polynomial on all \mathbb{R}^2 (and even at infinity, i.e. the associated homogeneized matrix polynomial remains positive definite).

Assume that N can be written as in (1) :

$$\begin{aligned} N &= \sum_{i=1}^r f_i(x, y) \begin{pmatrix} A_i^2 & A_i B_i \\ A_i B_i & B_i^2 \end{pmatrix} \\ &+ \sum_{j=1}^r g_j(x, y) \begin{pmatrix} U_j^2 & U_j V_j \\ U_j V_j & V_j^2 \end{pmatrix} \\ &+ \sum_{k=1}^r \begin{pmatrix} R_k^2 & R_k S_k \\ R_k S_k & S_k^2 \end{pmatrix} \end{aligned}$$

where the f_i 's are polynomials of degree at most 4, the g_j, R_k, S_k 's are polynomials of degree at most 2, the U_j, V_j 's are polynomials of degree at most 1 and the A_i, B_i 's are constant. Moreover, the polynomials f_i, g_j are assumed to be non negative on \mathbb{R}^2 . Since their degrees are at most 4 and the number of variables is 2, we know that they are sum of squares of polynomials. Hence, we may assume that

$$(3) \quad N = \sum_{i=1}^r \begin{pmatrix} R_i^2 & R_i S_i \\ R_i S_i & S_i^2 \end{pmatrix}$$

where

$$\begin{cases} R_i = a_i + b_i x + c_i x^2 + d_i y + e_i y^2 + f_i xy, \\ S_i = \alpha_i + \beta_i x + \gamma_i x^2 + \delta_i y + \nu_i y^2 + \mu_i xy, \\ (a_i, b_i, c_i, d_i, e_i, f_i, \alpha_i, \beta_i, \gamma_i, \delta_i, \nu_i, \mu_i) \in \mathbb{R}^{12}. \end{cases}$$

Let us consider the following vectors in the usual eucliden space \mathbb{R}^r :

$$\begin{aligned}\bar{a} &= (a_i), \bar{b} = (b_i), \bar{c} = (c_i), \bar{d} = (d_i), \bar{e} = (e_i), \bar{f} = (f_i), \\ \bar{\alpha} &= (\alpha_i), \bar{\beta} = (\beta_i), \bar{\gamma} = (\gamma_i), \bar{\delta} = (\delta_i), \bar{\nu} = (\nu_i), \bar{\mu} = (\mu_i).\end{aligned}$$

Identifying the non diagonal entries in (3), we get

$$(4) \quad \bar{b} \cdot \bar{\delta} + \bar{\beta} \cdot \bar{d} + \bar{a} \cdot \bar{\mu} + \bar{f} \cdot \bar{\alpha} = 1$$

where \cdot denotes the usual inner product on \mathbb{R}^r .

By identifying the diagonal entries in (3) and by the Cauchy-Schwarz inequality, we get

$$\left\{ \begin{array}{llll} \bar{b}^2 &= 1 - 2\bar{a} \cdot \bar{c} &\leq 1 + 2\sqrt{\bar{a}^2}\sqrt{\bar{c}^2} &\leq 1 + 2\sqrt{\epsilon} \\ \bar{\delta}^2 &= -2\bar{\alpha} \cdot \bar{\nu} &\leq 2\sqrt{\bar{\alpha}^2}\sqrt{\bar{\nu}^2} &\leq 2\sqrt{\epsilon} \\ \bar{\beta}^2 &= 1 - 2\bar{\alpha} \cdot \bar{\gamma} &\leq 1 + 2\epsilon & \\ \bar{d}^2 &= -2\bar{a} \cdot \bar{c} &\leq 2\sqrt{\epsilon} & \\ \bar{a}^2 &= 1 & & \\ \bar{\mu}^2 &= -2\bar{\gamma} \cdot \bar{\nu} &\leq 2\sqrt{\epsilon} & \\ \bar{f}^2 &= -2\bar{c} \cdot \bar{e} &\leq 2\sqrt{\bar{c}^2}\sqrt{\bar{e}^2} &\leq 2\epsilon \\ \bar{\alpha}^2 &= \epsilon & & \end{array} \right.$$

Again, by the Cauchy-Schwarz inequality, we have :

$$\left\{ \begin{array}{ll} \bar{b} \cdot \bar{\delta} &\leq \sqrt{2(1 + 2\sqrt{\epsilon})\sqrt{\epsilon}} \\ \bar{\beta} \cdot \bar{d} &\leq \sqrt{2(1 + 2\epsilon)\sqrt{\epsilon}} \\ \bar{a} \cdot \bar{\mu} &\leq \sqrt{2\sqrt{\epsilon}} \\ \bar{f} \cdot \bar{\alpha} &\leq \sqrt{2\epsilon} \end{array} \right.$$

Thus, if we take ϵ small enough, then we get a contradiction to (4). Namely, N does not admit a certificate as in (1).

3.2. Semi-algebraic covering. Thus, even for positive definite matrix polynomials, a certificate (1) does not exist in general. Although, one may remark that such a certificate exists *locally* in our examples.

Look at example 3.1. When $|x| \geq |y|$, then consider the identity

$$\begin{pmatrix} 1 + x^2 & xy \\ xy & x^2 + y^4 \end{pmatrix} = \begin{pmatrix} x^2 & xy \\ xy & y^2 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + (x^2 - y^2 + y^4) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

whereas when $|y| \geq |x|$, then consider

$$\begin{pmatrix} 1 + x^2 & xy \\ xy & x^2 + y^4 \end{pmatrix} = \begin{pmatrix} 1 & xy \\ xy & x^2 y^2 \end{pmatrix} + x^2 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + (y^4 - x^2 y^2) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

Hence we are going to change our definition by considering a semi-algebraic covering of our space.

From now on, we will focus on *forms*, namely *homogeneous* polynomials.

Definition 3.3. Let $f(x, y)$ be a biform of type $(n, d_1; m, d_2)$. A semi-certificate of positivity is the data of a semi-algebraic covering $\mathbb{R}^n = S_1 \cup \dots \cup S_r$ such that

$$\forall x \in S_i, \quad f(x, y) = \sum_{j=1}^{r_i} f_{i,j}(x)(g_{j,i}(x, y))^2$$

where each $f_{i,j}(x)$ is a form of degree $e_{i,j}$ which is non negative on S_i and $g_{i,j}^2(x, y)$ is a biform of type $(n, d_1 - e_{i,j}; m, d_2)$.

Roughly speaking, the semi-certificate is a piecewise identity which is a sum of squares with respect to one set of variables y and only psd with respect to the other set of variables x .

For convenience, we may formulate what happens when we are dealing with matrix polynomials. The symmetric psd matrix polynomial $M(x) \in \mathbb{R}[x]^{m \times m}$ admits a semi-certificate if there exists a (finite) semi-algebraic covering $(S_i)_{1 \leq i \leq r}$ of \mathbb{R}^n and

$$(\forall i)(\exists r_i \in \mathbb{N})(\forall j \in \{1, \dots, s_i\})(\exists f_{i,j}(x) \in \mathbb{R}[x])(\exists U_{i,j}(x) \in \mathbb{R}[x]^{m \times m})$$

such that

$$(5) \quad \left(M(x) = \sum_{j=1}^{r_i} f_{i,j}(x) U_{i,j}^T(x) U_{i,j}(x) \right) \text{ and } (\forall x \in S_i, f_{i,j}(x) \geq 0)$$

In example 3.1, we have seen that it is possible to produce semi-certificate of positivity, where the considered semi-algebraic covering of \mathbb{R}^2 necessarily have more than one piece.

Remark 3.4. Note that if we restrict ourselves to certificates where the $U_{i,j}(x)$ are constant matrices, then we have a strictly smaller class of certificates. For instance, consider the matrix polynomial $\begin{pmatrix} x^2 & xy \\ xy & y^2 \end{pmatrix}$ which is psd on all \mathbb{R}^2 , which is obviously psd on a neighbourhood V of the point $(1, 1)$ (we may proceed likewise the neighbourhood of any given point).

Let us deshomogenize by setting $y = 1$, set for simplicity $V = [1, 1 + \epsilon[$, $\epsilon > 0$, and assume that

$$\begin{pmatrix} x^2 & x \\ x & 1 \end{pmatrix} = \sum_i f_i(x) \begin{pmatrix} \alpha_i^2 & \alpha_i \\ \alpha_i & 1 \end{pmatrix} + \sum_j g_j(x) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

where the f_i 's and g_j 's are univariate polynomials psd on V and $\alpha_i \in \mathbb{R}$.

Let

$$\begin{cases} f_i(x) = a_i + b_i(x - 1) + c_i(x - 1)^2 \\ g_j(x) = d_j + e_j(x - 1) + f_j(x - 1)^2 \end{cases}$$

Then

$$\begin{cases} x^2 &= \sum_i \alpha_i^2 f_i(x) + \sum_j g_j(x) \\ x &= \sum_i \alpha_i f_i(x) \\ 1 &= \sum_i f_i \end{cases}$$

Combining these three identities we get

$$\sum_i (\alpha_i - 1)^2 f_i(x) + \sum_j g_j(x) = (x - 1)^2$$

By assumption, we have $a_i \geq 0$ and $d_j \geq 0$. Then, for all j we have $d_j = 0$ and $e_j = 0$. Furthermore, if $\alpha_i \neq 1$, then $a_i = 0$ and also $b_i = 0$. But subtracting the last two equalities of the previous system yields

$$x - 1 = \sum_i (\alpha_i - 1) f_i(x)$$

a contradiction.

4. MAIN RESULTS

There is one case when semi-certificates exist : when the matrix polynomial is positive definite. Remind that it means that it is positive definite on the unit sphere or the associated projective space.

Theorem 4.1. *Let $A(x) \in (\mathbb{R}[x])^{m \times m}$ be a positive definite matrix polynomial. Then, there is a finite semi-algebraic covering of $\mathbb{R}^n = \cup_{i=1}^r S_i$, some forms $f_{i,j}(x) \in \mathbb{R}[x]$, some matrix polynomials $A_{i,j}(x) \in (\mathbb{R}[x])^{m \times m}$ such that,*

$$\forall x \in S_i, A(x) = \sum_{j=1}^{r_i} f_{i,j}(x) A_{i,j}^T(x) A_{i,j}(x)$$

with the condition that $f_{i,j}(x) \geq 0$ for all $x \in S_i$.

Proof. Assume that the entries of $A(x)$ are d -forms (d is even).

We start with a lemma

Lemma 4.2. *Let $a(x)$ be a positive definite d -form and $c(x)$ be a positive semi-definite d -form. Then, there exists $\epsilon > 0$ such that $a(x) - \epsilon c(x)$ remains positive definite.*

Proof. The d -form $\tilde{c}(x) = c(x) + x_1^d + \dots + x_n^d$ is positive definite and the subset $S_{\tilde{c}} = \{x \mid \tilde{c}(x) = 1\}$ is compact. Since $a(x) > 0$ on $S_{\tilde{c}}$ we have for all $x \in S_{\tilde{c}}$, $a(x) \geq m > 0$. Hence, for all x ,

$$a\left(\frac{x}{\sqrt[d]{\tilde{c}(x)}}, \frac{x}{\sqrt[d]{\tilde{c}(x)}}\right) \geq m > 0.$$

Then $a(x) - \frac{m}{2}\tilde{c}(x)$ is positive definite, which concludes the proof since $\tilde{c}(x) \geq c(x)$. \square

Let $A(x) = (a_{i,j}(x))_{1 \leq i,j \leq m}$. For a given $x_0 \in \mathbb{R}^n \setminus \{0\}$, the matrix $A(x)$ is positive definite in a semi-algebraic subset U_{x_0} which is open in the unit sphere S^{n-1} of \mathbb{R}^n .

Let U be the square matrix of size m whose all entries are equal to 1. By 4.2 and up to resizing U_{x_0} , we may assume that $B(x) = A(x) - \epsilon(x_1^d + \dots + x_n^d)U$ remains positive definite in U_{x_0} for ϵ small enough, and moreover that all entries of $B(x_0)$ are non-zero.

Let $B(x) = (b_{i,j}(x))_{1 \leq i,j \leq m}$. Assume that $b_{2,1}(x_0) > 0$. We may write $B(x_0) = b_{2,1}(x_0)C$ where $C \in \mathbb{R}^{m \times m}$ is positive definite. Let $h_{x_0}(x)$ be a d -form satisfying $h_{x_0}(x_0) = 1$. Then, by 4.2,

$$b_{2,1}(x)C - \epsilon_1 h_{x_0}(x) \text{Id}_m$$

remains positive definite for some small $\epsilon_1 > 0$.

Now write

$$B(x) = (b_{2,1}(x)C - \epsilon_1 h_{x_0}(x) \text{Id}_m) + \tilde{B}(x)$$

Since $\tilde{B}(x_0) = \epsilon_1 \text{Id}_m$, the matrix $\tilde{B}(x)$ is positive definite in an open semi-algebraic neighbourhood of x_0 which we still denote by U_{x_0} .

Then, $\tilde{B}(x) = (\tilde{b}_{i,j}(x))_{1 \leq i,j \leq m}$ is such that $\tilde{b}_{2,1}(x) = 0$.

Of course, we proceed likewise when $b_{2,1}(x_0) < 0$, writing $B(x_0) = -b_{2,1}(x_0)C$ where $C \in \mathbb{R}^{m \times m}$ is positive definite. Thus,

$$B(x) = (-b_{2,1}(x)C - \epsilon_1 h_{x_0}(x) \text{Id}_m) + \tilde{B}(x)$$

Then, we repeat the same process to get rid off all the $b_{i,j}(x)$'s such that $i \neq j$ and reduce, up to resize U_{x_0} , to the case where $B(x)$ is diagonal. Namely, there is an open semi-algebraic subset $U_{x_0} \subset S^{n-1}$ such that for all $x \in U_{x_0}$,

$$(6) \quad A(x) = \sum_k f_k(x) U_k^T U_k$$

where $U_k \subset \mathbb{R}^{m \times m}$ is a constant matrix and $f_k(x)$ is a d -form which is psd on U_{x_0} .

To conclude the proof, we extract a finite semi-algebraic covering by compactness of S^{n-1} .

By homogeneity, we extend the identities (6) to all $x \in \mathbb{R}^n$. Moreover, we may manage in order that the polynomials describing the U_{x_0} 's are forms, and hence the identity (6) is true on S_{x_0} , the cone in \mathbb{R}^n with origin 0 and basis U_{x_0} . Thus, we get a finite covering of \mathbb{R}^n . \square

Note that the proof gives an *open* semi-algebraic covering, and that the U_k 's are constant matrices.

Likewise, we have an analogous result for biforms :

Theorem 4.3. *Let $f(x, y) \in \mathbb{R}[x, y]$ be a positive definite biform of type $(n, d_1; m, d_2)$. Then, there is a finite semi-algebraic covering of $\mathbb{R}^n = \cup_{i=1}^r S_i$, some forms $f_{i,j}(x) \in \mathbb{R}[x]$, some biforms $g_{i,j}(x, y) \in \mathbb{R}[x, y]$ such that,*

$$\forall x \in S_i, f(x, y) = \sum_{j=1}^{r_i} f_{i,j}(x) (g_{i,j}(x, y))^2$$

with the condition that $f_{i,j}(x) \geq 0$ for all $x \in S_i$.

Proof. We proceed as in the proof of Theorem 4.1. We get rid of any monomial appearing in f with some odd power with respect to at least one indeterminate. \square

5. SEMI-CERTIFICATES ON ORTHANT-NEIGHBOURHOODS

We say that V is an *orthant-neighbourhood* of x_0 if it contains the intersection of a neighbourhood of x_0 and an orthant O_{x_0} centered at x_0 (i.e. a subset defined by an open condition $x = x_0 + (X_1, \dots, X_n) \in O_{x_0}$ if $\epsilon_1 X_1 > 0, \dots, \epsilon_n X_n > 0$ where $(\epsilon_1, \dots, \epsilon_n) \in \{-1, +1\}^n$). We will write that O_{x_0} is an orthant-neighbourhood of (x_0, ϵ)

The orthant-neighbourhoods fit naturally with the use of Taylor expansion formula. Let us recall it relatively to an orthant-neighbourhood (x_0, ϵ) for a matrix polynomial $A(x)$ whose entries are not necessarily homogeneous polynomials :

$$A(x_0 + \epsilon X) = \sum_{\alpha} \frac{(\epsilon X)^{\alpha}}{\alpha!} A^{(\alpha)}(x_0)$$

where we use the standart multi-index symbol for products. Under a condition of domination by the constant term, we will see how to derive some certificate on orthant-neighbourhoods.

Definition 5.1. *Let $A(x)$ be a matrix polynomial. Denote by Γ_{x_0} the set of all multi-indexes β which are minimal (for the lexicographic ordering) such that $A^{(\beta)}(x_0) \neq 0$.*

We say that $A(x)$ satisfies the domination condition at x_0 if for all multi-index α there is some multi-index $\beta \in \Gamma_{x_0}$ and a non negative real number $r_{\alpha,\beta}$ such that $\beta \leq \alpha$ and $r_{\alpha,\beta}A^{(\beta)}(x_0) \pm A^{(\alpha)}(x_0)$ is psd.

Note that $\Gamma_{x_0} = \{0\}$ when $A(x_0) \neq 0$ which simplifies the domination condition. Note also that if $\beta \in \Gamma_{x_0}$ then necessarily all its coordinates are even integers.

Finally, mention that to check positivity via the Taylor formula, it would be enough to have the domination condition for any multi-index α whose at least one component is odd.

A typical use of this domination condition appears in the following situation :

Proposition 5.2. *Let $A(x)$ be a psd matrix polynomial on a neighbourhood of x_0 . Then, $A(x)$ satisfies the domination condition at x_0 if and only if it admits a semi-certificate at x_0 where the $U_{i,j}(x)$'s appearing in (5) are constant matrices.*

Proof. Assume that $A(x)$ satisfies the domination condition at x_0 . Let V be an orthant-neighbourhood of (x_0, ϵ) . We have

$$A(x_0 + \epsilon X) = \sum_{\beta \in \Gamma_{x_0}} \sum_{\alpha \in \Delta_\beta \cup \{\beta\}} \frac{(\epsilon X)^\alpha}{\alpha!} A^{(\alpha)}(x_0)$$

where Δ_β is a subset of all multi-index α such that $\alpha > \beta$ (we have to be carefull that one multi-index α may be greater than several elements of Γ_{x_0}).

$$\begin{aligned} A(x_0 + \epsilon X) &= \sum_{\beta \in \Gamma_{x_0}} \left(\left(\epsilon^\beta \frac{X^\beta}{\beta!} A^{(\beta)}(x_0) \right) \left(1 - \sum_{\alpha \in \Delta_\beta} \epsilon^\beta \frac{\beta!}{\alpha!} X^{\alpha-\beta} r_{\alpha,\beta} \right) \right. \\ &\quad \left. + \sum_{\alpha \in \Delta_\beta} \frac{X^\alpha}{\alpha!} \left(\epsilon^\alpha A^{(\alpha)}(x_0) + r_{\alpha,\beta} A^{(\beta)}(x_0) \right) \right) \end{aligned}$$

Since $\epsilon^\beta = 1$, we obtain a semi-certificate on the orthant-neighbourhood V .

Conversely, assume that

$$A(x) = \sum_i f_i(x) V_i$$

where each V_i is a constant psd matrix and each f_i is non negative on a neighbourhood of x_0 . We write the Taylor expansion of f_i at x_0 :

$$f_i(x_0 + X) V_i = \left(\sum_\alpha \frac{X^\alpha}{\alpha!} f_i^{(\alpha)}(x_0) \right) \times V_i$$

For the matrix polynomial $f_i(x) V_i$, consider the set Γ_{x_0} . If $\beta \in \Gamma_{x_0}$, then $f_i^{(\beta)}(x_0) > 0$ and for any $\alpha > \beta$, we clearly have the existence of a positive real number $r_{\alpha,\beta}$ such that $r_{\alpha,\beta} f_i^{(\beta)}(x_0) \pm f_i^{(\alpha)}(x_0) \geq 0$. This is the domination condition. \square

Remark 5.3. Since positive definite matrices obviously satisfy the domination condition, we may recover a version of Theorem 4.1 with orthant-neighbourhoods. But, maybe (highly heuristic !) it will produce a lot more pieces for the covering, since (again roughly speaking) we need 2^{n-1} orthant-neighbourhoods to recover a usual neighbourhood.

5.1. Semi-certificates relative to a semi-algebraic subset. One may naturally want to extend the framework of semi-certificates relatively to a basic closed semi-algebraic subset S . The problem is that the result given in this section does not take into account the equations describing S . We mainly use the underlying semi-algebraic set rather than the preordering or the quadratic module generated by the equations of S as it is desired for a relative Positivstellensatz. In fact, this section concerns more the study of *local* semi-certificates rather than *relative's* ones.

Theorem 5.4. *Let $A(x) \in \mathbb{R}[x]^{m \times m}$ be a homogeneous symmetric matrix polynomial. Assume that $A(x)$ is positive definite for all $x \in S$, where S is a closed semi-algebraically subset of \mathbb{R}^n defined by homogeneous polynomials. Then, there is a finite semi-algebraic covering of $S = \cup_{i=1}^r S_i$, some forms $p_{i,j}(x) \in \mathbb{R}[x]$, some homogeneous matrix polynomials $A_{i,j}(x) \in \mathbb{R}[x]^{m \times m}$ such that,*

$$\forall x \in S_i, A(x) = \sum_{j=1}^{r_i} p_{i,j}(x) A_{i,j}^T(x) A_{i,j}(x)$$

with the condition that $p_{i,j}(x) \geq 0$ for all $x \in S_i$.

Proof. We may perform the same proof as in Theorem 4.1. \square

As an example of a case where $A(x)$ is not definite, we consider a general matrix polynomial of degree at most 2 in a single (non homogeneous) variable x .

Example 5.5. Assume that $A(x)$ is psd in the neighbourhood of 0^+ .

We assume moreover that $A(0)$ is not positive definite otherwise we are done by 5.4 or by a domination argument. Up to a base change, we may assume that $A(0) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. Then, let us write

$$A(x) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + x \begin{pmatrix} a_1 & b_1 \\ b_1 & c_1 \end{pmatrix} + x^2 \begin{pmatrix} a_2 & b_2 \\ b_2 & c_2 \end{pmatrix} = \begin{pmatrix} 1 + a_1x + a_2x^2 & b_1x + b_2x^2 \\ b_1x + b_2x^2 & c_1x + c_2x^2 \end{pmatrix}$$

Since $A(x)$ is psd at 0^+ , we have $c_1 \geq 0$.

* If $c_1 > 0$, then the domination is satisfied and we get the following certificate

$$A(x) = (1 - \mu x - \alpha x^2) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + x \begin{pmatrix} a_1 + \mu & b_1 \\ b_1 & c_1 \end{pmatrix} + x^2 \begin{pmatrix} a_2 + \alpha & b_2 \\ b_2 & c_2 + \beta c_1 \end{pmatrix}$$

where α, β, μ are positive real numbers chosen such that the constant matrices of the identity are psd. Note that $(1 - \mu x - \alpha x^2)$ is obviously positive on a neighbourhood of 0^+ .

* If $c_1 = 0$, then $A(x)$ is psd on 0^+ if $c_2 - b_1^2 \geq 0$. If $c_2 - b_1^2 > 0$, then we have the certificate

$$A(x) = (1 - \alpha \epsilon x) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 1 - \epsilon & b_1 x \\ b_1 x & \frac{(b_1 x)^2}{1 - \epsilon} \end{pmatrix} + x^2 \begin{pmatrix} a_2 + \alpha \epsilon & b_2 \\ b_2 & c_2 - \frac{b_1^2}{1 - \epsilon} \end{pmatrix}$$

where ϵ and α are positive real numbers such that the last constant matrix in the identity is positive definite.

* Now, consider the case when $c_1 = 0$ and $c_2 - b_1^2 = 0$. By positivity of $A(x)$ we have $a_1c_2 - 2b_1b_2 \geq 0$.

The case when $b_1 = 0$ is trivial since we must have $b_2 = 0$ and the certificate follows. If $b_1 \neq 0$, then we get the condition $a_1b_1 - 2b_2 \geq 0$.

First assume that $a_1b_1 - 2b_2 > 0$. We may write

$$\begin{aligned} A(x) = & \left(x \left(a_1 - \frac{2b_2}{b_1} \right) + x^2 \left(a_2 - \left(\frac{b_2}{b_1} \right)^2 \right) \right) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \\ & + \begin{pmatrix} \left(1 + \frac{b_2}{b_1}x \right)^2 & (b_1x) \left(1 + \frac{b_2}{b_1}x \right) \\ (b_1x) \left(1 + \frac{b_2}{b_1}x \right) & (b_1x)^2 \end{pmatrix} \end{aligned}$$

* In the remaining case when $c_1 = 0$, $c_2 - b_1^2 = 0$, $b_1 \neq 0$, $a_1b_1 - 2b_2 = 0$, the positivity of $A(x)$ at 0^+ says that $a_2b_1^2 - b_2^2 \geq 0$. The desired certificate follows from the identity given in the previous case.

This inspection of the most elementary situation leads to conjecture that any matrix polynomial in a single variable admits a local certificate of positivity.

We give a proof of this fact, although we do not give explicit formulas depending on the entries as in the previous worked example.

Theorem 5.6. *Let $M \in \mathbb{R}[x]^{n \times n}$ be a symmetric matrix polynomial whose entries are polynomials in a single variable x . Assume that M is psd on a neighbourhood of 0^+ .*

Then, M admits a semi-certificate of positivity at 0^+ .

Proof. If $M(0)$ is invertible, then we are done by 4.1. Hence, from now on, we assume that $\det(M(0)) = 0$.

Let us consider the Smith normal form of M :

$$M = EDF$$

where E and F are invertible in $\mathbb{R}[x]^{n \times n}$ and $D = \text{diag}(d_1, \dots, d_n)$ is diagonal in $\mathbb{R}[x]^{n \times n}$ with diagonal entries (d_1, \dots, d_n) . By changing M to $(F^T)^{-1}MF^{-1}$, we may assume that $M = ED$. Moreover, if $d_i \equiv 0$ then we may argue by induction on the size of M , hence we will assume in the following that $d_i \geq 0$ at 0^+ and vanishes only at 0.

The matrix M has the form

$$M = \begin{pmatrix} d_1 e_{1,1} & d_2 e_{1,2} & \dots & d_n e_{1,n} \\ d_2 e_{1,2} & d_2 e_{2,2} & \dots & d_n e_{2,n} \\ \vdots & & & \vdots \\ d_n e_{1,n} & d_n e_{2,n} & \dots & d_n e_{n,n} \end{pmatrix}$$

Hence the matrix E has the form

$$E = \begin{pmatrix} e_{1,1} & e_{1,2} & \dots & & e_{1,n} \\ \frac{d_2}{d_1} e_{1,2} & e_{2,2} & \dots & & e_{2,n} \\ \vdots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \vdots \\ \frac{d_n}{d_1} e_{1,n} & \frac{d_n}{d_2} e_{2,n} & \dots & \frac{d_n}{d_{n-1}} e_{2,n} & e_{n,n} \end{pmatrix}$$

First, let us introduce some notations.

Define by induction the following sequence of integers :

Let $k_0 = 1$ and set k_i to be the first integer $j > k_{i-1}$ such that $\frac{d_j}{d_{j-1}}(0) = 0$. It yields an increasing sequence of integers :

$$1 = k_0 < k_1 < \dots < k_r \leq n = k_{r+1} - 1.$$

We divide the matrix $M = (m_{k,l})_{1 \leq k,l \leq n}$ into block matrices : $M = (M_{i,j})_{0 \leq i,j \leq r}$, where we set $M_{i,j} = (m_{k,l}^{(i,j)})_{1 \leq k \leq k_{i+1}-k_i, 1 \leq l \leq k_{j+1}-k_j}$ with $m_{k,l}^{(i,j)} = m_{k+k_i-1, l+k_j-1}$. Likewise, we divide $E = (E_{i,j})_{0 \leq i,j \leq r}$ into similar block matrices.

Let us define the block matrix $M_i = (R_{k,l})_{0 \leq k,l \leq r}$ such that $R_{k,l} = M_{k,l}$ when $(1 \leq k \leq i \text{ and } l = i) \text{ or } (1 \leq l \leq i \text{ and } k = i)$ and $R_{k,l} = 0$ otherwise. Namely

$$M_i = \begin{pmatrix} 0 & \dots & 0 & M_{1,i} & 0 & \dots & 0 \\ \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & \dots & 0 & M_{i-1,i} & \vdots & & \vdots \\ M_{i,1} & \dots & M_{i,i-1} & M_{i,i} & \vdots & & \vdots \\ 0 & \dots & \dots & \dots & 0 & \dots & 0 \\ \vdots & & & & \vdots & & \vdots \\ 0 & \dots & \dots & \dots & 0 & \dots & 0 \end{pmatrix}.$$

Let us write now

$$M = d_{k_0} M_0 + d_{k_1} M_1 + \dots + d_{k_r} M_r.$$

Observe then by construction that $E(0)$ is block upper triangular. Since $E(0)$ is invertible we get that $E_{i,i}(0)$ is invertible for each $i = 0, \dots, r$.

Moreover, we have

$$(7) \quad \det(M_{i,i}) = \det(E_{i,i}) \times \prod_{j=k_i}^{k_{i+1}-1} d_j$$

By definition of the k_i 's, it implies that $\det(\frac{1}{d_{k_i}} M_{i,i})$ does not vanish at 0. Hence we may derive a kind of domination condition for the matrix M at 0^+ . Namely, let us write

$$\begin{aligned} M &= d_{k_0} M_0 - d_{k_1} \times \mu_1 \times \text{Id}_{k_0, k_1} - \dots - d_{k_r} \times \mu_r \times \text{Id}_{k_0, k_1} \\ &\quad + d_{k_1} (M_1 + \mu_1 \text{Id}_{k_0, k_1}) - d_{k_2} \times \mu_2 \times \text{Id}_{k_1, k_2} - \dots - d_{k_r} \times \mu_r \times \text{Id}_{k_1, k_2} \\ &\quad \vdots \\ &\quad + d_{k_r} (M_r + \mu_r \text{Id}_{k_0, k_r}) \\ &= d_{k_0} N_0 + d_{k_1} N_1 + \dots + d_{k_r} N_r \end{aligned}$$

where the μ_i 's are positive real numbers and $\text{Id}_{p,q}$ is the diagonal matrix in $\mathbb{R}^{n \times n}$ whose i -th diagonal entry is $+1$ if $p \leq i \leq q-1$ and 0 otherwise. Because of (7), we know that we can choose the μ_i 's such that the matrix polynomials N_i are psd on a neighbourhood of 0^+ .

Then, using the same argument as in Theorem 4.1, we complete the construction of a semi-certificate. \square

The result is no more true with more than one variable :

Proposition 5.7. *Let*

$$M(x, y) = \begin{pmatrix} 1 + x^2 - y^2 & -x \\ -x & y^2 \end{pmatrix}.$$

Then, $M(x, y)$ is psd for $x^2 \geq y^2 \geq 1$ and $x^2 \leq y^2 \leq 1$ although it does not admit a certificate in a neighbourhood of $(1^+, 1^+)$.

Proof. First note that $\det(M(x, y)) = (y^2 - 1)(x^2 - y^2)$ to conclude to the positivity domain of $M(x, y)$.

For convenience, let us consider the following change of variables $y = 1 + Y$ and $x = Y + H$. We also perform a base change to “simplify” the expression of $M(0, 0) = \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}$. Let $P = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ and $Q = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$. Then,

$$P \times M(0, 0) \times Q = \begin{pmatrix} 4 & 0 \\ 0 & 0 \end{pmatrix}$$

and thus let us introduce the following matrix

$$\begin{aligned} N(X, Y) &= P \times M(x, y) \times Q \\ &= \begin{pmatrix} 4 + 4H + 4Y + H^2 + Y^2 + 2HY & 2H - 2Y + H^2 - Y^2 + 2HY \\ 2H - 2Y + H^2 - Y^2 + 2HY & H^2 + Y^2 + 2HY \end{pmatrix} \end{aligned}$$

The matrix $N(X, Y)$ is psd at an orthant-neighbourhood $(0^+, 0^+)$ with respect to the variables (H, Y) . Let us assume that it has a semi-certificate of positivity. Namely :

$$(8) \quad N(X, Y) = \sum_i F_i \begin{pmatrix} \epsilon_i^2 & \epsilon_i \\ \epsilon_i & 1 \end{pmatrix} + \sum_j \begin{pmatrix} U_j^2 & U_j V_j \\ U_j V_j & V_j^2 \end{pmatrix} + G \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

where all F_i 's and G are psd on an orthant-neighbourhood $(0^+, 0^+)$. The degrees of the $(2, 2)$ -entries shows that each f_i has only monomials of degree 2 and each V_j has monomials of degree 1. Hence :

$$\begin{cases} F_i = a_i H^2 + b_i Y^2 + c_i H Y \\ U_j = \gamma_j + \mu_j H + \nu_j Y \\ V_j = \alpha_j H + \beta_j Y \\ G = a' H^2 + b' Y^2 + c' Y H + d' H + e' Y + f' \end{cases}$$

Identifying the $(2, 2)$ -entries, we get

$$(9) \quad \begin{cases} \sum_i a_i + \sum_j \alpha_j^2 = 1, \\ \sum_i b_i + \sum_j \beta_j^2 = 1 \\ \sum_i c_i + 2 \sum_j \alpha_j \beta_j = 2 \end{cases}$$

Identifying the coefficients in H and Y of the $(1, 2)$ -entries and the constant coefficients of the $(1, 1)$ -entries yields :

$$(10) \quad \begin{cases} \sum_j \alpha_j \gamma_j = 2 \\ \sum_j \beta_j \gamma_j = -2 \\ \sum_j \gamma_j^2 + f' = 4 \end{cases}$$

Let us introduce $\bar{\alpha} = (\alpha_j)$, $\bar{\beta} = (\beta_j)$ and $\bar{\gamma} = (\gamma_j)$, vectors of the standart euclidean space (whose dimension is equal to the number of indexes j).

After (10) and (9), we get

$$\bar{\gamma}^2 \leq 4, \quad \bar{\alpha}^2 \leq 1 \quad \text{and} \quad \bar{\alpha} \cdot \bar{\gamma} = 2.$$

By the Cauchy- Schwartz case of equality, we get $\bar{\gamma}^2 = 4$ and $\bar{\alpha}^2 = 1$. Thus, $f' = 0$ and $\sum_i a_i = 0$ which means that for all i , $a_i = 0$. Moreover, the vectors $\bar{\alpha}$ and $\bar{\gamma}$ must be colinear and hence $\bar{\alpha} = \frac{1}{2}\bar{\gamma}$.

Likewise $\bar{\beta} = -\frac{1}{2}\bar{\gamma}$ and $\sum_i c_i = 4$. Moreover, for all i we have $b_i = 0$. And hence we may assume that there is only one index i and we may write

$$(11) \quad N(X, Y) = 4HY \begin{pmatrix} \epsilon^2 & \epsilon \\ \epsilon & 1 \end{pmatrix} + \sum_j \begin{pmatrix} U_j^2 & U_j V_j \\ U_j V_j & V_j^2 \end{pmatrix} + G \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

Identifying the $(1, 2)$ -entries, and setting $\bar{\mu} = (\mu_j)$ and $\bar{\nu} = (\nu_j)$ we have

$$(12) \quad \begin{cases} \frac{1}{2}\bar{\gamma} \cdot \bar{\mu} = 1 \\ \frac{1}{2}\bar{\gamma} \cdot \bar{\nu} = 1 \\ \frac{\bar{\gamma}}{2} \cdot (\bar{\mu} - \bar{\nu}) + 4\epsilon = 2 \end{cases}$$

We readily deduce that $\epsilon = \frac{1}{2}$. Identifying the $(1, 1)$ -entry, we have furthermore

$$(13) \quad \begin{cases} 2\bar{\gamma} \cdot \bar{\mu} + d' = 4, \\ 2\bar{\gamma} \cdot \bar{\nu} + e' = 4, \\ 2\bar{\mu} \cdot \bar{\nu} + c' + 1 = 2, \\ \bar{\mu}^2 + a' = 1, \\ \bar{\nu}^2 + b' = 1, \end{cases}$$

By (12) and (13), we immediately have $d' = e' = 0$. Moreover, we get also

$$\bar{\gamma} \cdot \bar{\mu} = 2, \quad \bar{\mu}^2 \leq 1 \quad \text{and} \quad \bar{\gamma}^2 = 4.$$

By the Cauchy-Schwartz case of equality, we deduce that $a' = 0$ and $\bar{\mu} = \frac{1}{2}\bar{\gamma}$.

Likewise $b' = 0$ and $\bar{\nu} = \frac{1}{2}\bar{\gamma}$.

Then, $G = c'HY$ where necessarily $c' \geq 0$. To conclude, it suffices to note that $2\bar{\mu} \cdot \bar{\nu} + c' + 1 = 2$ gives $2 + c' + 1 = 2$, a contradiction. \square

Remember that any psd biquadratic form in dimension 2 is a sum of squares, and hence admits a semi-certificate. This example shows that the *local* counterpart is no more true.

In general we may mention the following result. Although completely elementary, it looks very much like the ones we can find in [7] or [8] for hermitian squares or more classical sums of squares.

Proposition 5.8. *Let $A(x) \in \mathbb{R}[x]^{m \times m}$ be a symmetric matrix polynomial. Then, $A(x)$ is psd if and only if for all real $\epsilon > 0$ the matrix polynomial*

$$A_\epsilon(x) = A(x) + \epsilon \left(\sum_{i=1}^n x_i^2 \right) \text{Id}_m$$

admits a semi-certificate.

Of course the complexity of the semi-certificate may increase as ϵ goes to zero.

Remark 5.9. The complexity of a semi-certificate shall be measured by the size of the semi-algebraic partitions and also by the number of squares. Here the degrees of the polynomials appearing in a (homogeneous) semi-certificate are bounded by the degree of the given matrix polynomial.

Remark 5.10. By [6] with respect to the (compact) unit sphere $\{\sum_{i=1}^n x_i^2 = 1\}$, then we obtain for M a Positivstellensatz which is no more homogeneous and where the degrees are no more bounded.

Remark 5.11. Consider a semi-certificate, and a compact semi-algebraic subset S_i of the given partition. If we assume that the description of S_i is archimedean, then we may deduce a “true” algebraic certificate without denominators for the matrix polynomial on S_i , using for instance Schmüdgen or Putinar certificates.

6. AROUND THE CHOI COUNTEREXAMPLE

Let us consider the counterexample of a biquadratic psd non sum of squares given in [1] :

$$\begin{pmatrix} x^2 + 2z^2 & -xy & -xz \\ -xy & y^2 + 2x^2 & -yz \\ -xz & -yz & z^2 + 2y^2 \end{pmatrix}$$

Although it is not a sum of squares, it admits a semi-certificate. Indeed, when $|x| \geq |z|$, it can be decomposed as

$$\begin{aligned} & \begin{pmatrix} x^2 & -xy & -xz \\ -xy & y^2 & yz \\ -xz & yz & z^2 \end{pmatrix} + 2 \begin{pmatrix} z^2 & 0 & 0 \\ 0 & x^2 & -yz \\ 0 & -yz & y^2 \end{pmatrix} \\ &= (-x, y, z)^T (-x, y, z) + 2(0, -z, y)^T (0, -z, y) \\ &+ 2z^2 \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} + 2(x^2 - z^2) \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \end{aligned}$$

And by symmetry, we deduce an analogous certificate when $|z| \geq |x|$.

Let us consider a variation around this example ; in the following proposition, the Choi counterexample is just M_1 :

Proposition 6.1. *Let*

$$M_\lambda = \begin{pmatrix} x^2 + (\lambda + 1)z^2 & -xy & -xz \\ -xy & y^2 + (\lambda + 1)x^2 & -yz \\ -xz & -yz & z^2 + (\lambda + 1)y^2 \end{pmatrix}$$

where $\lambda \in \mathbb{R}$.

Then, M_λ is never a sum of squares and it is psd if and only if $\lambda \in [0, +\infty[$. Moreover, $\det(M_0)$ is a psd non sos polynomial and M_λ admits a semi-certificate of positivity for any $\lambda \in]0, +\infty[$.

Proof. The exact argument as in [1] works to show that any M_λ is not a sum of squares. We may reproduce it for convenience. We translate our ramewok into the language of biforms, setting

$$f_{M_\lambda} = (x^2 + (\lambda + 1)z^2)S^2 - 2xyST - 2xzSU + (y^2 + (\lambda + 1)x^2)T^2 - 2yzTU + (z^2 + (\lambda + 1)y^2)U^2$$

Assume that $f_{M_\lambda} = \sum f_i^2$ where f_i is a bilinear form. Since there is no monomials x^2U^2 , y^2S^2 , z^2T^2 in f_{M_λ} , there is no such monomials in each f_i^2 , and hence no monomials xU , yS nor zT in each f_i . We may write $f_i = g_i + h_i$ were g_i depends only in the monomials xS , yT , zU and h_i depends only in the monomials xT , yU , zS .

Then, $f_{M_\lambda} = \sum (g_i + h_i)^2$ shows that

$$\sum_i g_i^2 = x^2S^2 + y^2T^2 + z^2U^2 - 2(xyST + yzTU + xzSU),$$

a contradiction since the right hand side of the equality takes negative values for $x = y = z = S = T = U = 1$.

The fact that M_0 is psd and not a sum of squares may also be shown directly by using the following consequence of the Cauchy-Binet formula.

Lemma 6.2. *Let $M(x)$ be a symmetric matrix polynomial. If M is a sum of squares, then its determinant is also a sum of squares.*¹

Proof. We first state the Cauchy-Binet formula.

Given matrices $A \in \mathbb{R}^{m \times s}$ and $B \in \mathbb{R}^{s \times m}$, the Cauchy-Binet formula states that

$$\det(AB) = \sum_S \det(A_S) \det(B_S)$$

where S ranges over all the subsets of $\{1, \dots, s\}$ with m elements, and A_S (respectively B_S) denotes the matrix in $\mathbb{R}^{m \times m}$ whose columns are the columns of A (respectively whose rows are the rows of B) with index from S .

If $M(x)$ is a sum of squares, then it can be written $M(x) = A^T(x)A(x)$ for some matrix polynomial $A(x) \in \mathbb{R}[x]^{s \times m}$. Then,

$$\begin{aligned} \det(M(x)) &= \sum_S \det(A(x)^T)_S \det(A(x)_S) \\ &= \sum_S \det(M_S(x)^T) \det(M_S) \\ &= \sum_S (\det(M_S))^2. \end{aligned}$$

□

¹The Cauchy-Binet formula shows even more : if M is a sum of squares, then *all* its principal minors are sums of squares.

Note that M_0 has as a determinant :

$$\det(M_0) = x^4y^2 + y^4z^2 + z^4x^2 - 3x^2y^2z^2$$

a variation of the celebrated Motzkin polynomial which is psd and not a sum of squares !

Thus, the matrix polynomial M_0 , which is clearly psd since all its principal minors are psd, cannot be a sum of squares since its determinant is not !

Thus, M_0 (and thus all M_λ for $\lambda \geq 0$) are psd matrix polynomial. Moreover,

$$\det(M_\lambda(1, 1, 1)) = \lambda(\lambda + 3)^2$$

which shows that M_λ is not psd for small $\lambda < 0$ and hence for all $\lambda < 0$.

Let us study now the existence of semi-certificate of positivity.

For $\lambda > 0$, the set of real singular points of $\det(M_\lambda)$ have projective coordinates is $[1 : 0 : 0]$, $[0 : 1 : 0]$ and $[0 : 0 : 1]$ (they correspond to the points where the non negative polynomial $\det(M_\lambda)$ vanishes). The identity

$$M_\lambda = \begin{pmatrix} x^2 & -xy & -xz \\ -xy & y^2 & yz \\ -xz & yz & z^2 \end{pmatrix} + \begin{pmatrix} \lambda z^2 & 0 & 0 \\ 0 & \frac{4z^2}{\lambda} & -2yz \\ 0 & -2yz & \lambda y^2 \end{pmatrix} + \frac{1}{\lambda}(\lambda x^2 - 4z^2) \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

gives a semi-certificate at the neighbourhood of $[1 : 0 : 0]$. We may also proceed likewise at the neighbourhood of $[0 : 1 : 0]$ and $[0 : 0 : 1]$.

Elsewhere the matrix M_λ is positive definite so that we can argue as in the proof of Theorem 4.1 and obtain a finite semi-algebraic covering, and hence a semi-certificate.

Whereas, the matrice M_0 has a lot more singular points, namely : $[1 : 0 : 0]$, $[0 : 1 : 0]$, $[0 : 0 : 1]$, $[1 : 1 : 1]$, $[1 : 1 : -1]$, $[1 : -1 : 1]$, $[1 : -1 : -1]$.

So, the problem which remains is to find a certificate of positivity for M_0 at the points $[1 : 1 : 1]$, $[1 : 1 : -1]$, $[1 : -1 : 1]$, $[1 : -1 : -1]$. It does not appear trivial. For instance, the domination condition is not satisfied here. Another natural idea would be to consider :

$$\begin{aligned} M_0 &= \begin{pmatrix} x^2 + z^2 & -xy & -xz \\ -xy & y^2 + x^2 & -yz \\ -xz & -yz & z^2 + y^2 \end{pmatrix} \\ &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & y^2 & -yz \\ 0 & -yz & y^2 \end{pmatrix} + \begin{pmatrix} y^2 & -xy & 0 \\ -xy & x^2 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\ &\quad + \begin{pmatrix} x^2 + z^2 - y^2 & 0 & -xz \\ 0 & 0 & 0 \\ -xz & 0 & y^2 \end{pmatrix} \end{aligned}$$

But, setting $z = 1$ in the last matrix, we get a matrix polynomial which is psd at an orthant-neighbourhood of $(1^+, 1^+)$ with respect to the variables (x, y) , but which does not admit any semi-certificate as shown by Proposition 5.7.

Nevertheless, let us see in the following how it is possible to get a semi-certificate in some orthant-neighbourhood of $[1 : 1 : 1]$, and hence a partial result.

Let $z = 1$ and $x = 1 + X$, $y = 1 + Y$. Write the Taylor formula at $(1, 1)$:

$$M_0 = A_0 + XA_1 + X^2A_2 + YB_1 + Y^2B_2 + XYC_2$$

Consider the following matrices :

$$A_X = \frac{5}{12}A_0 + XA_1 + X^2A_2 = \begin{pmatrix} \frac{5}{6} + 2X + X^2 & -\frac{5}{12} - X & -\frac{5}{12} - X \\ -\frac{5}{12} - X & \frac{5}{6} + 2X + X^2 & -\frac{5}{12} \\ -\frac{5}{12} - X & -\frac{5}{12} & \frac{5}{6} \end{pmatrix}$$

$$A_Y = \frac{5}{12}A_0 + YB_1 + Y^2B_2 = \begin{pmatrix} \frac{5}{6} & -\frac{5}{12} - Y & -\frac{5}{12} \\ -\frac{5}{12} & \frac{5}{6} + 2Y + Y^2 & -\frac{5}{12} - Y \\ -\frac{5}{12} & -\frac{5}{12} - Y & \frac{5}{6} + 2Y + Y^2 \end{pmatrix}$$

$$A_{XY} = \frac{2}{12}A_0 + XYC_2 = \begin{pmatrix} \frac{1}{3} & -\frac{1}{6} - XY & -\frac{1}{6} \\ -\frac{1}{6} - XY & \frac{1}{3} & -\frac{1}{6} \\ -\frac{1}{6} & -\frac{1}{6} & \frac{1}{3} \end{pmatrix}$$

One may check that

$$C_X = A_X - A_0 \left(\frac{X}{4} - X^2 \right) = \begin{pmatrix} \frac{18X^2+9X+5}{6} & \frac{-12X^2-9X-5}{12} & \frac{-12X^2-9X-5}{12} \\ \frac{-12X^2-9X-5}{12} & \frac{18X^2+9X+5}{6} & \frac{-12X^2+3X-5}{12} \\ \frac{-12X^2-9X-5}{12} & \frac{-12X^2+3X-5}{12} & \frac{12X^2-3X+5}{6} \end{pmatrix}$$

is positive semi-definite on all \mathbb{R} . Since it is a psd matrix polynomial with respect to the single variable X , it is a sum of squares.

Likewise, one may check that

$$C_Y = A_Y - A_0 \left(\frac{-Y}{4} - Y^2 \right) = \begin{pmatrix} \frac{12Y^2+3Y+5}{6} & \frac{-12Y^2-15Y-5}{12} & \frac{-12Y^2-3Y-5}{12} \\ \frac{-12Y^2-15Y-5}{12} & \frac{18Y^2+15Y+5}{6} & \frac{-12Y^2-15Y-5}{12} \\ \frac{-12Y^2-3Y-5}{12} & \frac{-12Y^2-15Y-5}{12} & \frac{18Y^2+15Y+5}{6} \end{pmatrix}$$

is positive semi-definite on all \mathbb{R} . Since it is a psd matrix polynomial with respect to the single variable Y , it is a sum of squares.

Finally, write

$$A_{XY} = \left(\frac{2(1+6XY)}{12} A_0 \right) - XY(A_0 - C_2)$$

Where we check that $(A_0 - C_2)$ is a psd constant matrix.

If we sum up all these informations, we obtain a desired certificate of positivity

$$M_0 = A_X + A_Y + A_{XY} = A_0 \left(\frac{X}{4} - X^2 \right) + C_X + A_0 \left(\frac{-Y}{4} - Y^2 \right) + C_Y + A_{XY}$$

with respect to the open orthant-neighbourhood of $(0,0)$ defined by $X > 0$ and $Y < 0$.

Likewise, we may produce a local certificate with respect to the orthant defined by $X < 0$ and $Y > 0$).

But, it seems less clear how to obtain a local certificate with respect to the orthants defined by $XY > 0$.

□

7. CONCLUDING REMARKS

7.1. Open questions about semi-certificates. We have introduced the notion of piecewise semi-certificate of positivity for matrix polynomials. For the moment, the only general result is that all positive definite matrix polynomial admit such a certificate. A lot of things remain to be studied.

- We shall better understand the set of all psd matrix polynomials which admit a semi-certifiacte. Beginning with biquadratic forms for instance ?
- We shall develop some effective algorithm to produce the certificates.
- About the complexity of certificates : how can we bound the number of squares, and also the number of pieces of the semi-algebraic partition ?

On the other hand, one may also rise some questions about the family of psd polynomials which have a quadratic determinantal representation. This is the object of the last subsection :

7.2. Semi-definite quadratic determinatal representations. In the spirit of what happens in Proposition 6.1, one may be interested in determining what psd polynomial can be written as the determinant of a psd quadratic matrix polynomial (whose entries are homogeneous polynomials of degree 2). Namely,

Question 7.1. Let $f(x) \in \mathbb{R}[x]$ be a form of degree $2d$ which is suppose to be non negative. Does-there exists a quadratic matrix polynomial $M(x) \in \mathbb{R}[x]^{d \times d}$ which is psd for all $x \in \mathbb{R}^n$ and such that

$$(14) \quad f(x) = \det(M(x))?$$

One motivation for such a question is that it appears as the quadratic analogous of very classical linear determinantal representations which have been studied for a very long time. The specifically real considerations being more recents and essentially du to Vinnikov (see for instance [11] and all related papers). Let us recall that these have a lot of applications for instance to Linear Matrix Inequalities, convex modelling, etc...

On the other hand, biquadratic forms are a quite common object found at various areas in ingenering applications. For instance, any determinantal representation as in (14) of a psd non sum of squares polynomial provides, by Cauchy-Binet formula, another example of a psd biquadratic form which is not a sum of squares.

Of course, a simple count on the number of parameters shows Question 7.1 has a negative answer in general.

We can be even more precise : if f is a form of degree 4 in 4 variables, such a representation never exists when f is psd non sum of squares. Indeed, if $f =$

$\det(M(x))$ with $M(x) \in \mathbb{R}[x]^{2 \times 2}$, then $M(x)$ is a psd biquadratic form which is a sum of squares (in dimension 2), hence $\det(M)$ is a sum of squares of polynomials by Cauchy-Binet formula.

We may also look at the trivial case when $n = 2$, which we may deshomogenize for simplicity. The answer to Question 7.1 is clearly positive by an elementary argument. Indeed, let us write

$$f(x) = \sum_{i=0}^{2d} a_i x^i = \prod_j (x - \alpha_j)^2 \times \prod_k (x + \beta_k)^2 + \gamma_k^2$$

Then, the result follows obviously from the multiplicative property of the determinant and the fact that the $(x - \alpha_i)^2$'s and the $(x + \beta_k)^2 + \gamma_k^2$'s are psd quadratic polynomials.

We may even give a more algorithmic construction (a polynomial time algorithm with respect to the size of the coefficients of the polynomial) using arrows matrices and following [5] and [9].

Back to Question 7.1, and before expecting general results, one may wonder if for instance the celebrated Motzkin and Robinson polynomials

$$\begin{cases} \text{Mo} = z^6 + x^2 y^4 + x^4 y^2 - 3 x^2 y^2 z^2 \\ \text{Ro} = x^6 + y^6 + z^6 - x^4 y^2 - x^4 z^2 - y^4 x^4 - y^4 z^2 - z^4 x^2 - z^4 y^2 + 3 x^2 y^2 z^2 \end{cases}$$

can be written as in (14) ?

It is quite easy, using for instance the linear well-know determinantal representations of cubics curves, to produce quadratic determinantal representations for these two polynomials, but unfortunately none such representation yields a *psd* quadratic matrix polynomial.
